Background

empiric (ĕm-pîr' ĭk) n. 1. That depending upon the observation of phenomena. 2. An unqualified or dishonest practitioner; a charlatan.

Background

empiric (ĕm-pîr' ĭk) n. 1. That depending upon the observation of phenomena. 2. An unqualified or dishonest practitioner; a charlatan.

Theoretical Basis

Background

empiric (ĕm-pîr' ĭk) n. 1. That depending upon the observation of phenomena. 2. An unqualified or dishonest practitioner; a charlatan.

Theoretical Basis

The rich are not like us. F. Scott Fitzgerald

Yes, they have more money. Ernest Hemingway

Regional Convergence Studies

- σ Convergence (Williamson, 1965)
 - measures dispersion = income gap
 - 2nd moment of distribution
 - ignores mixing
 - ignores geographical distribution

Regional Convergence Studies

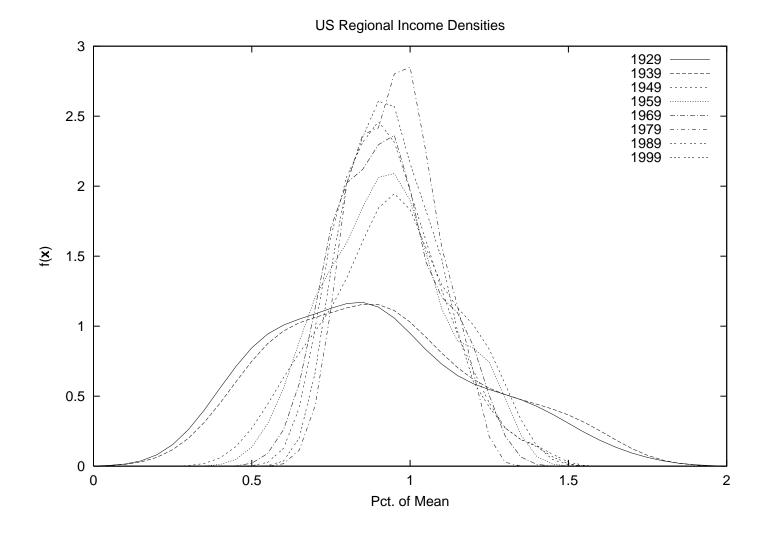

- σ Convergence (Williamson, 1965)
 - measures dispersion = income gap
 - 2nd moment of distribution
 - ignores mixing
 - ignores geographical distribution
- β Convergence (Barro and Sala-i-Martin, 1991)

$$\frac{1}{k} \cdot \ln \left(\frac{y_{i,t+k}}{y_{i,t}} \right) = \alpha - \beta \cdot \ln \left(y_{i,t} \right) + \psi X_{i,t} + \epsilon_{i,t} \tag{1}$$

- conditional vs. unconditional
- neoclassical basis

- "Newer Approaches"
 - Stochastic convergence (Bernard and Jones, 1996)
 - Markov Chains (Quah, 1993, 1996a,b)
 - Mixture Models (Tsionas, 2000)

- "Newer Approaches"
 - Stochastic convergence (Bernard and Jones, 1996)
 - Markov Chains (Quah, 1993, 1996a,b)
 - Mixture Models (Tsionas, 2000)
- Treatment of Space?
 - Spatial dependence
 - β : (Rey and Montouri, 1999; Fingleton, 2001)
 - Spatial heterogeneity
 - β : (Chatterji and Dewhurst, 1996; Sala-i-Martin, 1996)
 - Spatial scale

Markov Chains

- focus on transitional dynamics
- higher order moments of distribution
- accommodates shocks, discontinuities and turbulence

$$P_{t+b} = P_t M^b \tag{2}$$

$$P_{t+b} = P_t M^b$$

$$P_t = [p_{1,t}, p_{2,t} \dots p_{k,t}], \sum_{i=1}^k p_{i,t} = 1$$
(3)

$$M = \begin{bmatrix} m_{1,1} & m_{1,2} & \dots & m_{1,k} \\ m_{2,1} & m_{2,2} & \dots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ m_{k,1} & m_{k,2} & \dots & m_{k,k} \end{bmatrix}$$
(4)

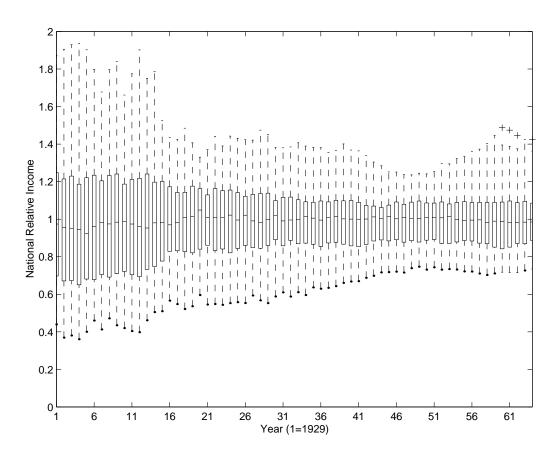

$$\sum_{j=1}^{k} m_{i,j} = 1 \ \forall i$$

Space and Markov Chains

- spatial effects
 - dependence
 - * chains based on independence assumption
 - * + dependence = inflated deviance
 - heterogeneity?
- Quah's regional conditioning
 - national-relative distribution
 - regional-relative distribution
 - results
 - * regional conditioning = less dispersion
 - * accounts for variation in (national)distribution

- national-regional relative
- the two should be identical under spatial independence assumption

Nationally Conditioned Distributions

Regionally Conditioned Distributions

Issues

- Problem
 - Quah's national-regional transition is static but spatial
 - dynamics?
- Solution
 - Local Indicators of Spatial Association (LISAs) (Anselin, 1995)
 - Integrate into Markov Chain framework

LISAs

$$I_i = z_i \sum_{i=1}^n w_{i,j} z_j \tag{5}$$

Table 2: LISA Classifications

Class	Own Value	Neighbors' Value
HH	Above Average	Above Average
HL	Above Average	Below Average
LH	Below Average	Above Average
LL	Below Average	Below Average

Moran Scatterplot

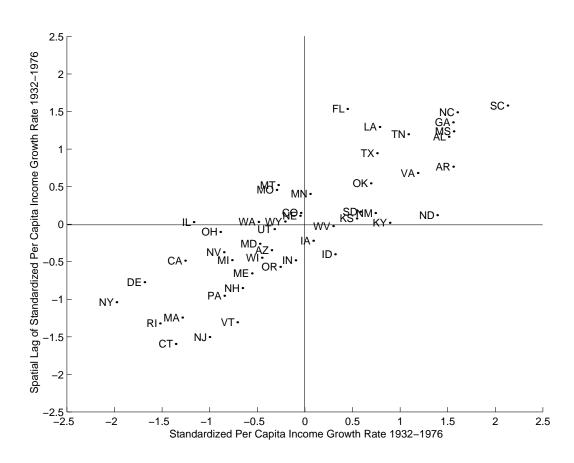

Table 3: Spatial Transitions

11	11 LL		State	
12	LL	НН	Both	Ш

Spatial Flux:

$$n = F_{0,t} + F_{I,t} + F_{II,t} + F_{III,t}. (6)$$

$$RF_0 < RF_I < RF_{II} < RF_{III} \tag{7}$$

Spatial Stability:

$$S_t = \frac{F_{0,t}}{n}.$$
(8)

Spatial Cohesion

$$C_t = \frac{F_{IIIA,t}}{n} \tag{9}$$

$$C_t^* = \frac{F_{IIIA,t} + F_{0,t}}{n} \tag{10}$$

Table 4: A Spatial Markov Matrix

	State	t_1		
Lag	t_0	Low	Med.	High

Mobility

- 1. Regional Income Mobility
 - Class Mobility
 - Mixing (Rank Mobility)
- 2. Spatial Issues
- 3. New Measures
 - (a) Trace = Spatial Dependence (Static)
 - (b) External Regional Cohesion = Dependence (Dynamic)
 - (c) Internal Regional Cohesion = Dependence (Dynamic)
- 4. Illustration: Lower 48 States 1929-99

Why Mobility Matters

- Class Mobility
 - σ convergence
 - twin peaks (Quah, 1996a)
 - mixtures?
- Rank Mobility
 - Leap-frogging
 - Cohesion versus flux

Spatial Issues

- Income distributions vs. Spatial distributions
- Moments robust spatial pattern?
- Modality robust to spatial pattern?
 - at one point in time
 - changes in moments vs. changes in pattern?
 - $\rightarrow dynamics$

- Inference and spatial dependence
 - stochastic kernels
 - mixture modeling
 - *i.i.d* versus space?

Class Mobility

$$M_{t,t+s} = \begin{pmatrix} m_{11} & \dots & m_{1k} \\ m_{21} & \dots & m_{2k} \\ \vdots & \vdots & \vdots \\ m_{k1} & \dots & m_{kk} \end{pmatrix}$$
(12)

where m_{ij} are the probabilities of a region making the transition from income class i to class j over the period t to t+s.

Table 9: Estimated Annual Transition Matrix, US 1929-99

	Class									
n	0.59	0.79	0.89	1.10	∞					
158	0.87	0.13	0.00	0.00	0.00					
565	0.02	0.88	0.09	0.01	0.00					
635	0.00	0.07	0.82	0.11	0.00					
1409	0.00	0.00	0.05	0.93	0.02					
593	0.00	0.00	0.00	0.06	0.94					

Shorrock (1978) mobility index:

$$SI = \frac{k - Tr\left(M_{t,t+s}\right)}{k - 1} \tag{13}$$

where Tr indicates the trace operator.

- 0 <= SI <= 1.25
- US: 0.141
- 1929 quintiles mapped to 1999:
 0, 5, 11, 25, 6
- upward convergence

Role of Space

More attention needed on two fronts.

Substantive

- Do growth spill-overs exist?
- Is growth regionally competitive or regionally cooperative?
 Or, both?
- Interregionally competitive vs. intraregionally cooperative?
- Poverty Traps, Convergence Clubs, Regional Cohesion

Measures

- spatial dependence in regional income distributions.
- the role of regional context in income mobility

Regional Conditioning

- Quah (1993)
- one point in time
- relative incomes
 - nationally conditioned income

$$y_{r,t}^{N} = \frac{y_{r,t}}{\sum_{s} y_{s,t}/n} \tag{14}$$

- regionally conditioned income

$$y_{r,t}^{R} = \frac{y_{r,t}}{\sum_{s} w_{r,s} y_{s,t}}$$
 (15)

$$M_{R,N} = \begin{pmatrix} m_{R1,N1} & \dots & m_{R1,Nk} \\ m_{R2,N1} & \dots & m_{R2,Nk} \\ \vdots & \vdots & \vdots \\ m_{Rk,Nk} & \dots & m_{Rk,Nk} \end{pmatrix}$$
(16)

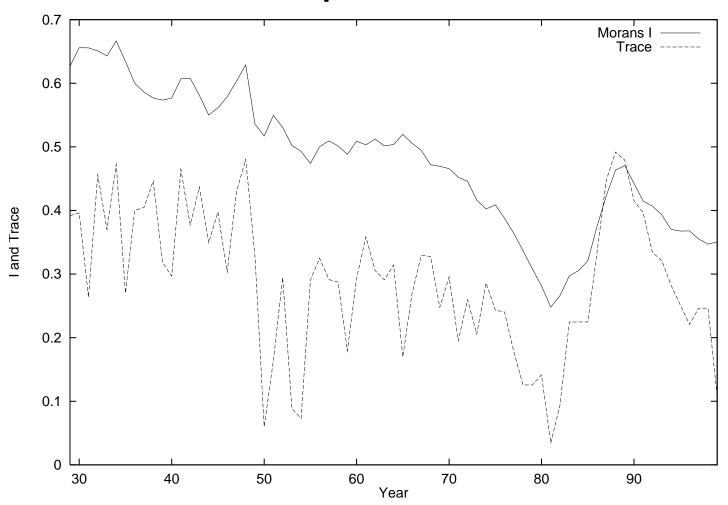

- diagonality = spatial randomness
- intuitive, no formal statistic suggested

$$\zeta = 1 - \sum_{l}^{k} M_{l,l} \tag{17}$$

$$0 \le \zeta \le 1$$

•	inference	based	on ranc	lom sp	atial pe	ermutat	ions.			
						Univers	ity of Queen	sland, School	of Econom	ics Seminar
						0	, or accom	, 55.1001		

Trace Test for Spatial Autocorrelation

Results: ζ

- Both tests display general downward trend
- Both tests pick up during 1980s
- Moran's I significant each year
- ζ significant 68 (0.1), 62 (0.05), 53 (0.01)

Spatial Rank Mobility

Let $\theta_{i,t}$ represent the rank of state i's per-capita income in year t. Then between any two periods, a scalar measure of spatial clustering of distributional transitions is:

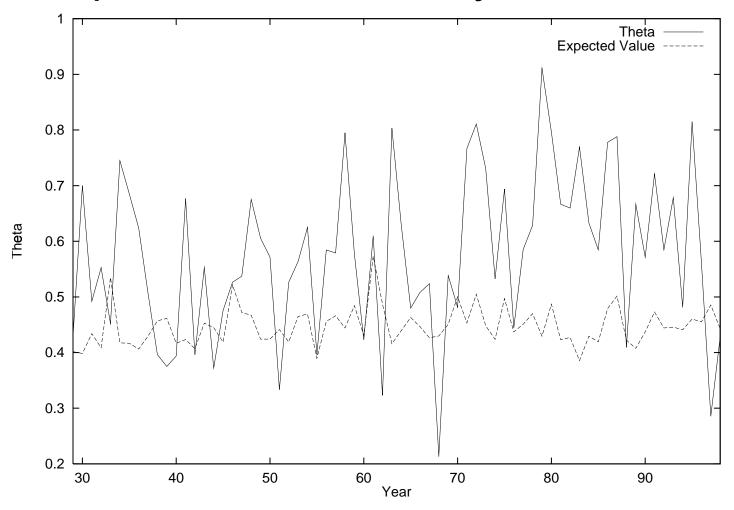

$$\Theta_{t1-t0} = \frac{\sum_{R} \left| \sum_{i \in R} \theta_{i,t1} - \theta_{i,t0} \right|}{\sum_{i} \left| \theta_{i,t1} - \theta_{i,t0} \right|}$$
(18)

where R is one of a set of exhaustive and mutually exclusive groups of states.

$$0 \le \Theta_{t1-t0} \le 1$$

 $Random \iff Cohesion$

Spatial Cohesion Index: 1-year Interval

Results: Θ

- $\Theta > E[\Theta]$ (56 of 70)
- Significant differences in 27, 23, 12 years
- Before 1968 Θ averages 0.54, after 0.61
- ullet Before 1968, $E\left[\Theta\right]$ averages 0.445, after 0.451

Decomposition of Spatial Rank Mobility

Kendall's τ is given as:

$$\tau = \frac{N_c - N_d}{(n^2 - n)/2} \tag{19}$$

where N_c is the number of concordant pairs, and N_d the number of discordant pairs. If all pairs are concordant, then $N_c=(n^2-n)/2$, $N_d=0$ and $\tau=1$, while if all pairs are discordant, then $\tau=-1$.

$$N_c = N_{c,r} + N_{c,o} (20)$$

where $N_{c,r}$ is the number of concordant pairs involving locations belonging to the same region, and $N_{c,o}$ are the number of concordant pairs for

observations belonging to different regions. A similar decomposition holds for the discordant pairs N_d . To develop a spatial version of the τ statistic from equation (19), define:

$$\omega = (n^2 - n)/2 \tag{21}$$

which is the denominator in the original form of the statistic. This is also equal to the number of elements above (or below) the main diagonal in the spatial weights matrix. Each element in that matrix specifies whether observations i and j are considered members of the same region (or more generally neighbors). The sum of these elements can also be decomposed:

$$\omega = \omega_r - \omega_o \tag{22}$$

where ω_r is the number of pairs of observations that are members of the

same region. From this a spatial version of the rank mobility measure is:

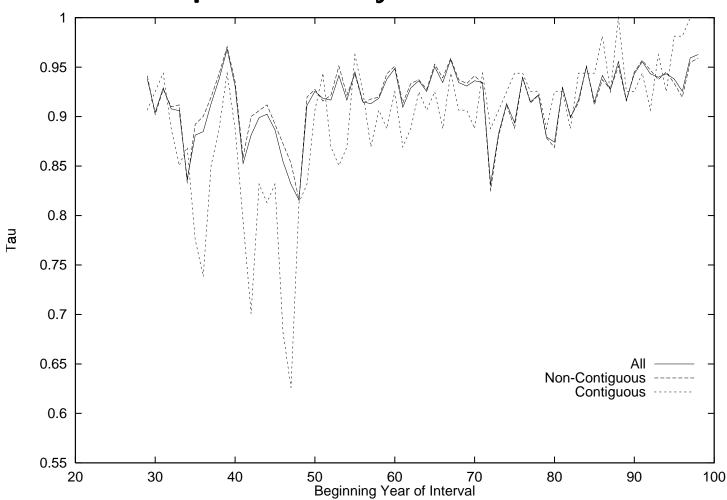

$$\tau_r = \frac{N_{c,r} - N_{d,r}}{\omega_r} \tag{23}$$

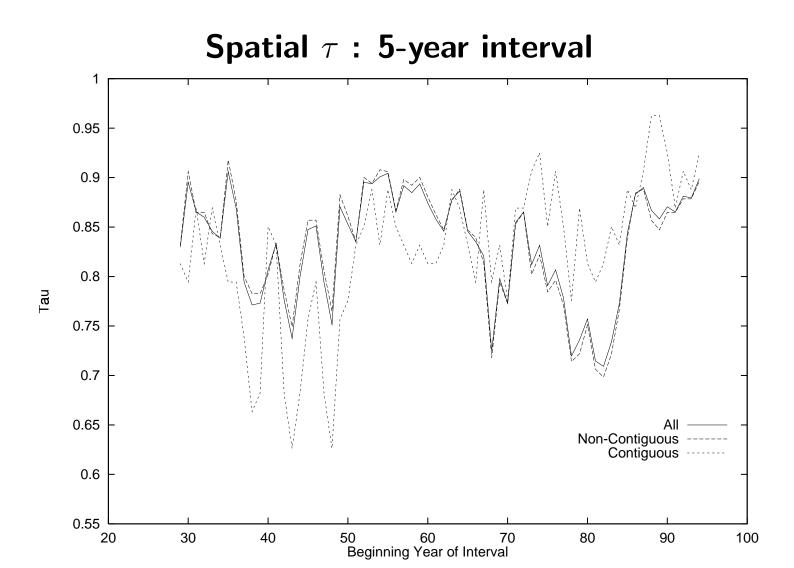

A similar measure can be derived for the non-neighbor pairs of observations τ_o . The original measure of rank mobility can then be decomposed as follows:

$$\tau = \psi \tau_r + (1 - \psi)\tau_o \tag{24}$$

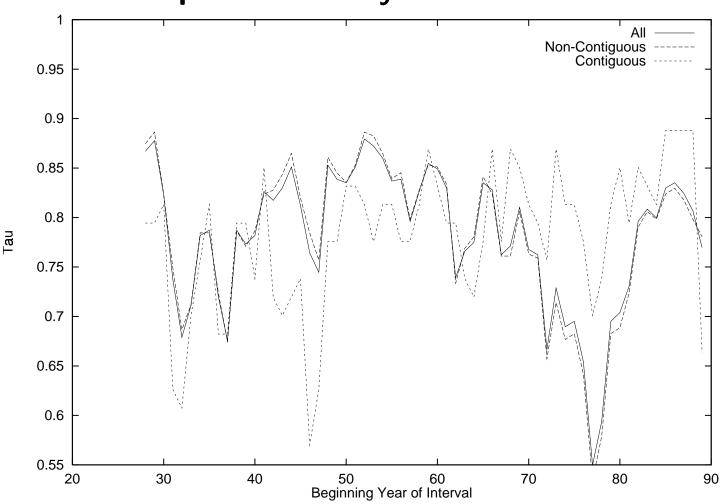

with $\psi = \omega_r/\omega$.

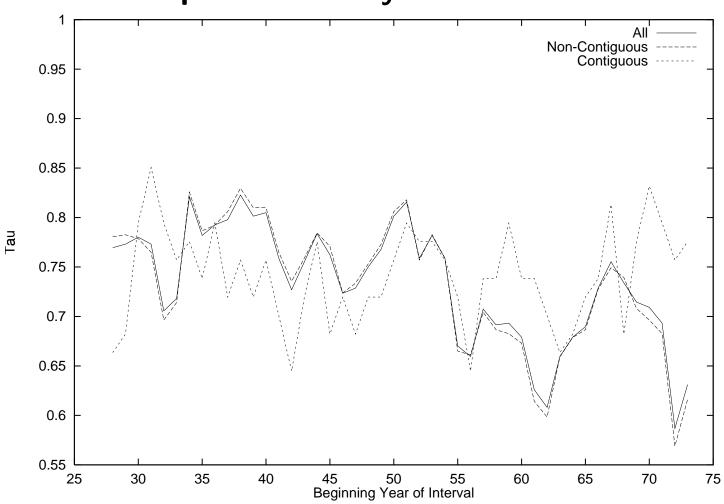

Spatial τ : 10-year interval

Spatial τ : 25-year interval

Results: Spatial τ

- Mobility increases with interval length
- Early, $\tau_r < \tau_o$
- Late, $\tau_r > \tau_o$
- Spatial dependence and dispersion greater in beginning of period.
